Amendment and the rule of *People v. Kelly* (1976) 17 Cal. 3d 24,
and *Frye v. United States*, 293 F. 1013 (D.C. Cir. 1923).

Dated: April 16, 2012

Respectfully submitted,
RONALD L. BROWN, PUBLIC DEFENDER

By 
HARRY J. McKEE
Deputy Public Defender

INTRODUCTION

1
2
3 Firearms Examiner W. Moore has concluded that the
4 markings he observed on a single discharged cartridge casing
5 purportedly recovered from an apartment where the defendant
6 was residing was "discharged in the same firearm" as
7 discharged cartridge casings recovered at the scene of the
8 shooting. (See attached Lab Report dated April 21, 2011).
9
10 Mr. Moore reached this conclusion without having analyzed
11 any actual firearm. (See generally attached Arrest Report).
12
13 Mr. Moore also opined that bullets recovered from the
14 right rear passenger door of the complaining witness'
15 vehicle and a bullet recovered from the front door at
16 10812 ½ Magnolia were "fired through the barrel of the
17 same firearm". (See attached Lab Report dated August 30,
18 2011; see also attached Property Report dated March 30,
19 2011; see also attached Property Report dated March 30,
20 2011; see also attached Property Report dated July 19,
21 2011; see also attached Property Report dated July 19,
22 2011).
23
24

25 The defense objects to this language because it
26 communicates to the fact finder a proposition not
27 generally accepted in the relevant scientific community¹:
28 that the examiner was able to determine based on a single
29 side-by-side comparison that these cartridges were
30
31
32

33 _____
34 ¹ This is the standard for admissibility under Kelly-Frye.

"discharged from the same firearm" to the exclusion of all others. The defense seeks to exclude such testimony.

This Motion explains why the proposition that one particular firearm can be singled out based on markings observed on a piece of ammunition is controversial in the relevant scientific community, why identification opinions are not generally accepted and thus violate Kelly/Frye, and why the defense's proposed exclusion on Mr. Moore's testimony is generally accepted.

1 Finally, individual characteristics are toolmarks which
2 are believed to be *unique* to a single tool and
3 *reproducible* from a single tool so that individual marks
4 reproduced on different fired cartridges can be used to
5 show that these cartridges were all fired by the same
6 firearm. The theory as to their creation is that they
7 originate from random imperfections in the manufacturing
8 process or subsequent use, corrosion or damage. However,
9 these two fundamental assumptions of uniqueness and
10 reproducibility of individual marks are not accepted even
11 within the community of firearm examiners. (See attached
12 Affidavit of Alicia Carriquiry, Ph.D).

13
14
15
16 C. Assumptions are Not Accepted Even Within
17 the Firearms Examiner Community

18 In the Association of Firearm and Toolmark
19 Examiners [*hereinafter* "AFTE"] journal in Spring of 2000,
20 FATM examiner Jerry Miller carried out thousands of
21 comparisons of bullets of different calibers of known
22 matches and known non-matches. See *Jerry Miller Criteria*
23 *for Identification of Toolmarks Part II Single Land*
24 *Impression Comparisons* AFTE Journal Spring 2000. Mr.
25 Miller's objective was to establish that the least
26 subjective methodology used by firearm examiners, known as
27 CMS, produces few false positive identifications and that
28 its performance does not depend on caliber. In his
29 research, Mr. Miller obtained the distribution of the
30 percentages of land impression matches (minimum, average,
31
32
33
34

1 maximum) over the thousands of comparisons for known
2 matches (KM) and known non-matches (KNM) samples. His
3 results are striking in that they put into question
4 whether an examiner who is only counting matching land
5 impressions can accurately declare that two samples match.
6

7 Instead, Mr. Miller's results suggest that there is a
8 similar distribution of matching impressions among bullets
9 that are known to be matches as there are among bullets
10 known to be non-matches. Given that with both known
11 matches and known non-matches, the percentages of matching
12 landmarks were similar, it is clear that simply by
13 counting the number of matching markings between two
14 samples, it is not possible to accurately declare a match
15 between the two samples. See Jerry Miller *Criteria for*
16 *Identification of Toolmarks, supra.*
17
18
19

20 For example, with regard to the data obtained by
21 Miller for 9mm ammunition using two-dimensional images,
22 the range in the number of matching striae was 2 to 9 in
23 KNM and 1 to 27 in KM. The corresponding average numbers
24 were 5 and 7. Now while the maximum number of matching
25 striae appears to be much higher in KM (27 versus 9 in
26 KNM), the relatively low average of 7 indicates that much
27 of the distribution of the number of matching impressions
28 was actually concentrated around the lower values.
29
30 Therefore, given two samples with anywhere between two and
31 ten matching impressions, it would be equally likely for
32 them to be a "true" match or a "true" non-match. See
33
34

1 Jerry Miller *Criteria for Identification of Toolmarks*,
2 supra.
3

4 Miller's results call into question the
5 reliability of FATM examinations in generating a match.
6 For most calibers and for both two and three-dimensional
7 images, experimental data suggests that the overlap
8 between the distribution in numbers, and percentages, of
9 matching impressions in KMs and KNMs is too high to allow
10 for separating a match from a non-match. See Jerry Miller
11 *Criteria for Identification of Toolmarks*, supra.
12

13
14 Additionally, the community of FATM practitioners
15 has ignored those in their own circles who have expressed
16 concern that "[a]s the techniques of firearms manufacture
17 have evolved, following mostly commercial rather than
18 forensic arguments, this hypothesis [of uniqueness] needs
19 to be verified on a regular basis." See M.S. Bonfanti &
20 J. De Kinder, *The Influence of Manufacturing Processes on*
21 *the Identification of Bullets and Cartridge Cases - A*
22 *Review of the Literature*, 39 *Sci. & Justice* 4 (1999). In
23 other words, because the aim of firearm manufacturers is
24 to make as many firearms as similar as possible, and
25 because techniques of mass production have facilitated
26 this goal, the assumption of uniqueness needs to be
27 verified on a continuing basis as manufacturing techniques
28 change. See United States v. Mouzone, Crim. No. WDQ-08-
29 086, reprinted in and adopted by United States v. Willock,
30 696 F.Supp.2d 536, 574 (D. Md. 2010).

33
34

1 D. National Academy of Sciences Questioning
2
3 the Validity of Assumptions

4 From 2004 to 2007, Dr. Carriquiry served on a
5 Committee of the National Academy of Sciences, charged
6 with assessing the technical feasibility of a national
7 ballistics database. The project was sponsored by the
8 National Institute of Justice (NIJ), the Office of Justice
9 Programs and the US Department of Justice. This study
10 culminated with an exhaustive 322 page treatise on the
11 feasibility of a national ballistics database entitled
12 "Ballistics Imaging" (2008) which can be found at:
13 http://www.nap.edu/openbook.php?record_id=12162&page=197
14

15 Underlying the specific tasks with which the
16 committee was charged was the assumption of uniqueness of
17 firearms-related marks: ie. whether a particular set of
18 toolmarks can be shown to come from one weapon to the
19 exclusion of all others. The committee determined that
20 the validity of the fundamental assumptions of uniqueness
21 and reproducibility of firearms-related toolmarks has not
22 yet been fully demonstrated. The committee further found
23 that a significant amount of research would be needed to
24 scientifically determine the degree to which firearms-
25 related toolmarks are unique or even to quantitatively
26 characterize the probability of uniqueness. The Committee
27 stated that "[c]onclusions drawn in firearms
28 identification should not be made to imply the presence of
29 a firm statistical basis when none has been demonstrated."
30
31
32
33
34

1 *Id.* at 82. Further, it stated that "additional general
2 research on the uniqueness and reproducibility of
3 firearms-related toolmarks would have to be done if the
4 basic premises of firearms identifications are to be put
5 on a more solid scientific footing." *Id.*
6
7

8 In 2009, the National Academy of Sciences released
9 a second report entitled *Strengthening Forensic Science in*
10 *the United States: A Path Forward* (2009) which further
11 addressed and underscored the substantial debate within
12 the scientific community regarding the validity of
13 firearms toolmark identification.
14

15 After reviewing the literature offered by firearms
16 examiners in support of these fundamental assumptions, the
17 National Research Council ["NRC"] concluded that "the
18 scientific knowledge base for toolmark and firearms
19 analysis is fairly limited." (See *Strengthening Forensic*
20 *Science, supra* at 155). Specifically, the NRC found that
21 the "validity of the fundamental assumptions of uniqueness
22 and reproducibility of firearms-related toolmarks has not
23 yet been fully demonstrated." *Id.* at 154.¹ In other words,
24 the NRC found that the fundamental assumptions underlying
25 the firearm comparison discipline have not been shown to
26 be scientifically sound. Even if one were to assume that
27 there is some validity to the proposition that marks left
28 by a firearm are reproducible - that "firearms-related
29
30
31
32

33 Quoting NRC, *Ballistic Imaging, supra* at 3.
34

1 toolmarks are not completely random and volatile; one can
2 find similar marks on bullets and cartridge cases from the
3 same gun" - the NRC was very clear that reproducibility
4 alone is not sufficient to make the leap from a set of
5 marks on a bullet to one particular firearm. Id.
6

7
8 This is because, as the NRC discovered, there is
9 currently no scientific basis for the firearm examiner's
10 assumption of uniqueness. The NRC was unequivocal that a
11 "significant amount of research would be needed" not only
12 to "determine the degree to which firearms-related
13 toolmarks are unique" but even just to "characterize the
14 probability of uniqueness." Id. at 154.
15

16
17 The NRC was critical of the smattering of "studies"
18 that do exist, disapproving of their "heavy reliance on
19 the subjective findings of examiners rather than on the
20 rigorous quantification and analysis of sources of
21 variability [in the production of tool marks]." Id. at
22 155. This is unacceptable to the broader scientific
23 community, which demands that theoretical assumptions be
24 validated through empirical research before they can be
25 relied upon with any confidence in application. Id. at
26 112 (describing the essential processes of hypothesis
27 testing, methodical data collection, and developing limits
28 of uncertainty). And yet, firearms examiners not only
29 rely upon these assumptions with confidence, they rely
30 upon them with an unfounded "certainty."
31
32
33
34

1 The courts have also recognized that "[t]here is a
2 substantial debate within the scientific community, as
3 well as the Courts, regarding the degree to which firearms
4 toolmark identification evidence passes muster," and "in
5 this debate . . . the latest scientific consensus is as
6 expressed in the NRC Forensic Science Report." See United
7 States v. Mouzone, Crim. No. WDQ-08-086, reprinted in and
8 adopted by United States v. Willock, 696 F.Supp.2d 536,
9 574 (D. Md. 2010).

10
11
12
13
14 **II. THE FUNDAMENTAL ASSUMPTIONS OF UNIQUENESS AND**
15 **REPRODUCIBILITY LACK EMPIRICAL SUPPORT**

16
17 There is a lack of data to determine the
18 probability that two bullets or cartridge cases will match
19 if fired from the same firearm. (See attached Affidavit
20 of Alicia Carriquiry, Ph.D). As discussed earlier, the
21 significance of a match in terms of probative value relies
22 on the assumption that each gun leaves a "unique" mark or
23 impression on all bullets or cartridges fired with it (ie
24 the assumptions of uniqueness and reproducibility). These
25 are unverified assumptions because with the data that
26 exists it is not possible to determine the probability
27 that two bullets or cartridge cases will match if fired
28 from different guns. This is known as the coincidental
29 match probability. It is crucial to know if this

99
100

1 before knowing the probative value of a match.
2

3 In the case of DNA evidence, it is known both:
4 (1) the probability that two samples will match if they
5 were deposited by the *same person*; and (2) the probability
6 that 2 samples will match if they were deposited by
7 *different persons*. The ratio of these two probabilities
8 is the *likelihood ratio* and the likelihood ratio is very
9 high for DNA because the first probability is very high
10 and the second probability (coincidental match
11 probability) is very low.
12
13

14 With firearm marks examining, there is no known
15 likelihood ratio because there is insufficient data to
16 know the coincidental match probability: the probability
17 that two samples will match if they originated from
18 different firearms. In order to reliably estimate the
19 coincidental match probability for firearm examining, it
20 is necessary to conduct a *population-wide* study where a
21 representative sample of guns (ie each type of each brand
22 of firearm) with a wide range of ammunition to create a
23 *reference database* as exists in DNA (which has shown that
24 the coincidental match probability in that field is
25 essentially zero).
26
27
28

29 Just as in its infancy DNA evidence was not
30 supported by a reference database from which a
31 coincidental match could be estimated, firearm marks
32 examining evidence of "matches" should not be allowed
33
34

1 until a reference database is established.
2
3

4 **III. THE FATM METHODOLOGY IS FLAWED WITH SUBJECTIVITY**
5 **AND LACKS VALIDATION**

6
7 Aside from the lack of acceptance of the fundamental
8 assumptions of uniqueness and reproducibility, scientists
9 do not accept that the Association of Firearm and Toolmark
10 Examiners' (AFTE's) amorphous standards can be used to
11 reliably distinguish unique from non-unique markings and
12 use those markings to narrow the pool of potential sources
13 down to one particular firearm. The NRC examined the AFTE
14 "methodology":
15

16 AFTE has adopted a theory of identification, but
17 it does not provide a specific protocol. It says
18 that an examiner may offer an opinion that a
19 specific tool or firearm was the source of a
20 specific set of toolmarks or a bullet striation
21 pattern when "sufficient agreement" exists in the
22 pattern of two sets of marks. It defines
23 agreement as significant "when it exceeds the best
24 agreement demonstrated between tool marks known to
25 have been produced by different tools and is
26 consistent with the agreement demonstrated by tool
27 marks known to have been produced by the same
28 tool." The meaning of "exceeds the best
29 agreement" and "consistent with" are not
30
31
32
33
34

1 specified, and the examiner is expected to draw on
2 his or her own experience.
3

4 See *Strengthening Forensic Science*, supra at 155.

5
6 As the NRC points out, AFTE's guidance does not provide a
7 coherent methodology at all, but rather leaves it to the
8 examiner to make a "subjective decision based on
9 unarticulated standards." Id. at 153-55. The AFTE theory
10 asks the firearms examiner to think back to the closest
11 known non-match that he can remember, and see if the
12 correlation he currently sees under the microscope is
13 better than the one in his mind's eye. If so, it is
14 appropriate to opine that the marks came from one specific
15 firearm. That's it. That's the entirety of the guidance
16 provided under the AFTE theory of identification. Perhaps
17 not surprisingly even to the layperson, the scientific
18 community finds this "lack of a precisely defined process"
19 to be a "fundamental problem with toolmark and firearm
20 analysis." Id. at 155.
21
22
23

24 For example, for a firearms examiner to allege that
25 markings left on a bullet or cartridge case came from a
26 particular gun, he must have distinguished "individual"
27 markings from all non-individual markings, including
28 subclass markings, and also must have found enough of
29 these "individual" markings to warrant excluding all other
30 firearms. Subclass markings resemble individual markings
31 - indeed, they are created in the same fashion, by
32
33
34

1 imperfections in the firearms manufacturing process - but
2 unlike "individual" markings, they will be transferred to
3 bullets and cartridge casings fired from any firearm
4 manufactured in the same lot (i.e. produced by the same
5 tool).

6
7
8 Examples of problematic subclass characteristics
9 (i.e. markings that may appear to be unique but are actually
10 common to a specific make and model of gun) are rife in the
11 literature² and are publicly acknowledged to present serious
12 problems for the possibility of making correct
13 identifications.³ Nevertheless, the AFTE method fails to
14 provide any standards for recognizing or otherwise dealing
15 with subclass markings. "Because not enough is known about
16 the variabilities among individual tools and guns,"⁴ and

19
20 ² See, e.g., Patrick D. Ball, *Toolmarks Which May Lead to False Conclusions*, 32(3) AFTE J. 292 (2000);
21 Evan Thompson, *False Breech Face ID'S*, 28(2) AFTE J. 95 (1996); Richard K. Maruoka, *Guilty Before*
22 *the Crime? The Potential for a Possible Misidentification or Elimination*, 26(3) AFTE J. 206 (1994);
23 Richard K. Maruoka, *Guilty Before the Crime II?*, 27(1) AFTE J. 20 (1995); see also M.S. Bonfanti &
24 J. De Kinder, *The Influence of Manufacturing Processes on the Identification of Bullets and Cartridge*
25 *Cases - A Review of the Literature*, 39 Sci. & Justice 3, 5 (1999) (reporting that for some handguns
26 "a correct identification of the firearm on the basis of the breech face and firing pin impression, turned
27 out to be hardly possible" and for different guns "it was impossible to identify the tool which generated
28 the subclass characteristics").

29
30
31 ³ See, e.g., Gene C. Rivera, *Subclass Characteristics in Smith & Wesson SW40VE Sigma Pistols*, 39(3)
32 AFTE J. 247 (2007).

33
34 ⁴ *Strengthening Forensic Science*, supra at 154.

1 because the AFTE theory offers no standards to guide the
2 analysis, "subclass characteristics that could easily be
3 mistaken for individual characteristics, and might lead an
4 examiner to make a false positive identification" are a
5 serious problem.⁵
6

7
8 Not only does the AFTE method fail to provide a
9 defined process (or standards) for firearms examiners to
10 follow, worse, what guidance it does provide has not been
11 submitted to "any meaningful scientific validation,
12 determination of error rates, or reliability testing to
13 explain the limits of the discipline." See Strengthening
14 Forensic Science, supra at 107-08 (referring to firearms
15 comparison). Before scientists put a methodology to use,
16 they conduct validation testing to establish whether or
17 not the methodology reliably and consistently produces the
18 purported results. Validation testing also allows
19 scientists to determine the degree of certainty associated
20 with a methodology, i.e. the degree of certainty with
21 which a firearms examiner may match markings to one
22 particular firearm, assuming the methodology is executed
23 correctly.
24

25
26
27 Due to these limitations on - and the lack of
28 testing of - their methodology, firearms examiners have
29 not demonstrated that they can reliably identify a
30 particular firearm, nor what would be required to reliably
31
32

33
34 ⁵ See Rivera, *supra* n. 18, at 247.

1 identify a particular firearm. In the wake of the NRC's
2 report, even the president of the American Academy of
3 Forensic Sciences - the most comprehensive and respected
4 of the forensic science organizations (and the
5 organization that publishes the Journal of Forensic
6 Sciences) - agreed that "[t]ool mark analysis . . . can be
7 subject to validation but nevertheless appear[s] never to
8 have been studied for this purpose." See Thomas Bohan,
9 *President's Editorial: Strengthening Forensic Science: A Way Station on the Journey to*
10 *Justice*, 55(1) J. For. Sci. 2010 at 7. Because the AFTE theory has not
11 been validated, there is no way to assess its
12 "reliability, repeatability, or the number of correlations
13 needed to achieve a given degree of confidence" in a
14 "match." See *Strengthening Forensic Science*, supra at
15 155.

16
17
18
19
20 **IV. UNDER THE KELLY-FRYE TEST, FATM EXAMINERS SHOULD**
21 **NOT BE ALLOWED TO TESTIFY TO IDENTITY OR MATCH**
22 **OPINIONS**
23

24 In People v. Kelly (1976) 7 Cal 3d 24, the California
25 Supreme Court reaffirmed that in California, the test for
26 admissibility of expert testimony based on the application
27 of a new scientific technique comported with the federal
28 test set out in Frye v. United States 293 F. 1013, 1014
29 (D.C. Cir. 1923). The first of the three prongs requires
30 proof that the technique is generally accepted as reliable
31 in the relevant scientific community. A technique which
32
33
34

1 has enjoyed general acceptance may still be challenged
2 where "new evidence is presented reflecting a change in
3 attitude of the scientific community. See Kelly, supra at
4 32; see also People v. Bolden (2002) 29 Cal 4th 515, 545.
5

6
7 There is no serious question that there is a debate
8 in the relevant scientific community over the scientific
9 limitations on the firearm and toolmark discipline. On
10 one side of the divide stand independent scientists -
11 experts in the scientific method, proper experimental
12 design, measurements of certainty, and the manufacturing
13 processes employed in firearm production - as well as
14 forensic practitioners and heads of forensic laboratories.
15 After reviewing the firearm and toolmark methodology and
16 supporting literature, they found that the method has not
17 been validated - that the reliability and accuracy of the
18 method is unknown. They found that there is no basis in
19 science for identifying a particular source without
20 matching criteria or objective standards of any sort.
21
22

23
24 On the other side stand forensic firearm examiners,
25 beholden to the continued public trust in their discipline
26 for their bread and butter. In between the two sides lie
27 members of the firearm toolmark community, like Miller,
28 who have recognized the potential for mistakes and the
29 need for additional research.
30

31
32 The existence of a controversy in the relevant
33 scientific community is the beginning and the end of the
34

1 story in a Kelly-Frye jurisdiction such as this one. See
2 United States v. Jenkins, 887 A.2d 1013, 1022 (D.C. 2005).
3

4 Because there is a controversy as to whether a toolmark
5 examiner can match a bullet or cartridge casing to a
6 particular gun, the examiner cannot testify to such a
7 conclusion.
8

9 Recent opinions have heeded the admonitions of the
10 scientific community. For example, after an evidentiary
11 hearing the court in United States v. St. Gerard (U.S.
12 Army Tr. Judiciary, 5th Judicial Cir. June 7, 2010) found
13 that the examiner could not testify to a match to a
14 particular firearm **at all**, even if she refrained from
15 discussing her level of "certainty." Id. at 9-21.
16
17

18 Given the current estimation of the toolmarks
19 analysis discipline in the scientific community, a
20 firearms expert should not be permitted to testify to a
21 match to a particular firearm. Such formulations are not
22 generally accepted by the relevant scientific community.
23
24

25
26 **IV. THE DEFENSE PROPOSAL TO EXCLUDE THE EXAMINER'S**
27 **OPINION IS APPROPRIATE AND GENERALLY ACCEPTED**
28

29
30 Accordingly, in the present case, the FATM examiner
31 should not be allowed to render a cavalier identity or
32 match opinion as it is not accepted within the relevant
33
34

1 scientific community. At the very least, any opinion by
2 the examiner should be limited to what is accepted within
3 the relevant scientific community.
4

5
6
7 CONCLUSION
8

9
10 This Court should hold that, until the "pattern-
11 matching" methodology used by firearms examiners is
12 validated by the scientific community, *Kelly/Frye*
13 precludes the admission of expert testimony concluding
14 that marks on a bullet or casing were left by a particular
15 firearm. This court should exclude such identity
16 testimony entirely.
